Two Sum

Given an array of integers `nums` and an integer `target`, return indices of the two numbers such that they add up to `target`.

You may assume that each input would have exactly one solution, and you may not use the same element twice.

You can return the answer in any order.

Example 1:

Input: `nums = [2,7,11,15]`, `target = 9` Output: `[0,1]` Explanation: Because `nums[0] + nums[1] == 9`, we return `[0, 1]`.

Example 2:

Input: `nums = [3,2,4]`, `target = 6` Output: `[1,2]`

Example 3:

Input: `nums = [3,3]`, `target = 6` Output: `[0,1]`

Constraints:

```
2 <= nums.length <= 104
-109 <= nums[i] <= 109
-109 <= target <= 109
Only one valid answer exists.
```

<https://leetcode.com/problems/two-sum/description/>

Easy Solution

```
def easy_solution(nums: List[int], target: int) -> List[int]:
    # Brute-force solution: Check every pair of numbers
    for i in range(len(nums)):
        for j in range(i + 1, len(nums)):
            if nums[i] + nums[j] == target:
                return [i, j]
    return []
```

Optimized Solution

```
def optimized_solution(nums: List[int], target: int) -> List[int]:
    # Optimized solution: Use a dictionary to track numbers and their
indices
    num_dict = {}
    for i, num in enumerate(nums):
        complement = target - num
        if complement in num_dict:
            return [num_dict[complement], i]
        num_dict[num] = i
    return []
```

Time Complexity: $O(n)$ Space Complexity: $O(n)$

Two Sum II - Input array is sorted

3Sum

Given an integer array `nums`, return all the triplets `[nums[i], nums[j], nums[k]]` such that $i \neq j$, $i \neq k$, and $j \neq k$, and $nums[i] + nums[j] + nums[k] == 0$.

Notice that the solution set must not contain duplicate triplets.

Example 1:

Input: `nums = [-1,0,1,2,-1,-4]` Output: `[[-1,-1,2],[-1,0,1]]`

Example 2:

Input: `nums = []` Output: `[]`

Example 3:

Input: `nums = [0]` Output: `[]`

Constraints:

```
0 <= nums.length <= 3000
-105 <= nums[i] <= 105
```

<https://leetcode.com/problems/3sum/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> List[List[int]]:
    # Brute-force solution: Check all triplets
    result = []
    nums.sort()
    for i in range(len(nums) - 2):
        if i > 0 and nums[i] == nums[i - 1]:
            continue
        for j in range(i + 1, len(nums) - 1):
            if j > i + 1 and nums[j] == nums[j - 1]:
                continue
            for k in range(j + 1, len(nums)):
                if k > j + 1 and nums[k] == nums[k - 1]:
                    continue
                if nums[i] + nums[j] + nums[k] == 0:
                    result.append([nums[i], nums[j], nums[k]])
    return result
```

Optimized Solution

```
def optimized_solution(nums: List[int]) -> List[List[int]]:
    # Optimized solution: Use two pointers
    result = []
    nums.sort()
    for i in range(len(nums) - 2):
        if i > 0 and nums[i] == nums[i - 1]:
            continue
        left, right = i + 1, len(nums) - 1
```

```
while left < right:
    total = nums[i] + nums[left] + nums[right]
    if total == 0:
        result.append([nums[i], nums[left], nums[right]])
        while left < right and nums[left] == nums[left + 1]:
            left += 1
        while left < right and nums[right] == nums[right - 1]:
            right -= 1
        left += 1
        right -= 1
    elif total < 0:
        left += 1
    else:
        right -= 1
return result
```

Time Complexity: $O(n^2)$ Space Complexity: $O(1)$

Search in Rotated Sorted Array

There is an integer array `nums` sorted in ascending order (with distinct values).

Prior to being passed to your function, `nums` is possibly rotated at an unknown pivot index `k` ($1 \leq k < \text{nums.length}$) such that the resulting array is `[nums[k], nums[k+1], ..., nums[n-1], nums[0], nums[1], ..., nums[k-1]]` (0-indexed). For example, `[0,1,2,4,5,6,7]` might become `[4,5,6,7,0,1,2]`.

Given the array `nums` after the possible rotation and an integer `target`, return the index of `target` if it is in `nums`, or `-1` if it is not in `nums`.

You must write an algorithm with $O(\log n)$ runtime complexity.

Example 1:

Input: `nums = [4,5,6,7,0,1,2]`, `target = 0` Output: 4

Example 2:

Input: `nums = [4,5,6,7,0,1,2]`, `target = 3` Output: -1

Example 3:

Input: `nums = [1]`, `target = 0` Output: -1

Constraints:

```
1 <= nums.length <= 5000
-104 <= nums[i] <= 104
All values of nums are unique.
nums is an ascending array that is possibly rotated.
-104 <= target <= 104
```

<https://leetcode.com/problems/search-in-rotated-sorted-array/description/>

Easy Solution

```
def easy_solution(nums: List[int], target: int) -> int:
    # Brute-force solution: Use built-in index function
    return nums.index(target) if target in nums else -1
```

Optimized Solution

```
def optimized_solution(nums: List[int], target: int) -> int:
    # Optimized solution: Use binary search
    left, right = 0, len(nums) - 1
    while left <= right:
        mid = left + (right - left) // 2
        if nums[mid] == target:
            return mid
        if nums[left] <= nums[mid]:
            if nums[left] <= target < nums[mid]:
                right = mid - 1
            else:
                left = mid + 1
        else:
            if target <= nums[mid] < nums[right]:
                left = mid + 1
            else:
                right = mid - 1
```

```
        left = mid + 1
    else:
        if nums[mid] < target <= nums[right]:
            left = mid + 1
        else:
            right = mid - 1
    return -1
```

Time Complexity: $O(\log n)$ Space Complexity: $O(1)$

Product of Array Except Self

Given an integer array `nums`, return an array `answer` such that `answer[i]` is equal to the product of all the elements of `nums` except `nums[i]`.

The product of any prefix or suffix of `nums` is guaranteed to fit in a 32-bit integer.

You must write an algorithm that runs in $O(n)$ time and without using the division operation.

Example 1:

Input: `nums = [1,2,3,4]` Output: `[24,12,8,6]`

Example 2:

Input: `nums = [-1,1,0,-3,3]` Output: `[0,0,9,0,0]`

Constraints:

```
2 <= nums.length <= 105
-30 <= nums[i] <= 30
The product of any prefix or suffix of nums is guaranteed to fit in a
32-bit integer.
```

Follow up: Can you solve the problem in $O(1)$ extra space complexity? (The output array does not count as extra space for space complexity analysis.)

<https://leetcode.com/problems/product-of-array-except-self/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> List[int]:
    # Brute-force solution: Calculate product for each index
    n = len(nums)
    result = [1] * n
    for i in range(n):
        for j in range(n):
            if i != j:
                result[i] *= nums[j]
    return result
```

Optimized Solution

```
def optimized_solution(nums: List[int]) -> List[int]:
    # Optimized solution: Use left and right product arrays
    n = len(nums)
    result = [1] * n
    left_product = 1
    right_product = 1
    for i in range(n):
        result[i] *= left_product
        left_product *= nums[i]
        result[n - 1 - i] *= right_product
        right_product *= nums[n - 1 - i]
```

```
return result
```

Time Complexity: $O(n)$ Space Complexity: $O(1)$

Similar Questions

Trapping Rain Water
Maximum Product Subarray

Maximum Subarray

Given an integer array `nums`, find the subarray with the largest sum, and return its sum.

A subarray is a contiguous part of an array.

Example 1:

Input: `nums = [-2,1,-3,4,-1,2,1,-5,4]` Output: 6 Explanation: The subarray `[4,-1,2,1]` has the largest sum 6.

Example 2:

Input: `nums = [1]` Output: 1

Example 3:

Input: `nums = [5,4,-1,7,8]` Output: 23

Constraints:

```
1 <= nums.length <= 105
-104 <= nums[i] <= 104
```

<https://leetcode.com/problems/maximum-subarray/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> int:
    # Brute-force solution: Check all subarrays
    max_sum = float('-inf')
    for i in range(len(nums)):
        current_sum = 0
        for j in range(i, len(nums)):
            current_sum += nums[j]
            max_sum = max(max_sum, current_sum)
    return max_sum
```

Optimized Solution

```
def optimized_solution(nums: List[int]) -> int:
    # Optimized solution: Use Kadane's algorithm
    max_sum = current_sum = nums[0]
    for num in nums[1:]:
        current_sum = max(num, current_sum + num)
        max_sum = max(max_sum, current_sum)
    return max_sum
```

Time Complexity: $O(n)$ Space Complexity: $O(1)$

Maximum Product Subarray

Maximum Product Subarray

Given an integer array `nums`, find the contiguous subarray within an array (containing at least one number) which has the largest product.

Example 1:

Input: `nums = [2,3,-2,4]` Output: 6 Explanation: `[2,3]` has the largest product 6.

Example 2:

Input: `nums = [-2,0,-1]` Output: 0 Explanation: The result cannot be 2, because `[-2,-1]` is not a subarray.

Constraints:

```
1 <= nums.length <= 105
-10 <= nums[i] <= 10
The product of any prefix or suffix of nums is guaranteed to fit in a
32-bit integer.
```

<https://leetcode.com/problems/maximum-product-subarray/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> int:
    # Brute-force solution: Check all subarrays
    max_product = float('-inf')
    for i in range(len(nums)):
        current_product = 1
        for j in range(i, len(nums)):
            current_product *= nums[j]
            max_product = max(max_product, current_product)
    return max_product
```

Optimized Solution

```
def optimized_solution(nums: List[int]) -> int:
    # Optimized solution: Track max and min products
    max_so_far = min_so_far = result = nums[0]
    for i in range(1, len(nums)):
        temp_max = max(nums[i], max_so_far * nums[i], min_so_far *
nums[i])
        min_so_far = min(nums[i], max_so_far * nums[i], min_so_far *
nums[i])
        max_so_far = temp_max
        result = max(result, max_so_far)
    return result
```

Time Complexity: $O(n)$ Space Complexity: $O(1)$

Find Minimum in Rotated Sorted Array

Suppose an array of length n sorted in ascending order is rotated between 1 and n times. For example, the array `nums = [0,1,2,4,5,6,7]` might become:

`[4,5,6,7,0,1,2]` if it was rotated 4 times. `[0,1,2,4,5,6,7]` if it was rotated 7 times.

Notice that rotating an array `[a[0], a[1], a[2], ..., a[n-1]]` 1 time results in the array `[a[n-1], a[0], a[1], a[2], ..., a[n-2]]`.

Given the sorted rotated array `nums` of unique elements, return the minimum element of this array.

You must write an algorithm that runs in $O(\log n)$ time.

Example 1:

Input: `nums = [3,4,5,1,2]` Output: 1 Explanation: The original array was `[1,2,3,4,5]` rotated 3 times.

Example 2:

Input: `nums = [4,5,6,7,0,1,2]` Output: 0 Explanation: The original array was `[0,1,2,4,5,6,7]` and it was rotated 4 times.

Example 3:

Input: `nums = [11,13,15,17]` Output: 11 Explanation: The original array was `[11,13,15,17]` and it was rotated 4 times.

Constraints:

```
n == nums.length
1 <= n <= 5000
-5000 <= nums[i] <= 5000
All the integers of nums are unique.
nums is guaranteed to be rotated at some pivot.
```

<https://leetcode.com/problems/find-minimum-in-rotated-sorted-array/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> int:
    # Brute-force solution: Use built-in min function
    return min(nums)
```

Optimized Solution

```
def optimized_solution(nums: List[int]) -> int:
    # Optimized solution: Use binary search
    left, right = 0, len(nums) - 1
    while left < right:
        mid = left + (right - left) // 2
        if nums[mid] > nums[right]:
            left = mid + 1
```

```
        else:
            right = mid
    return nums[left]
```

Time Complexity: $O(\log n)$ Space Complexity: $O(1)$

Container With Most Water

You are given an integer array `height` of length `n`. There are `n` vertical lines drawn such that the two endpoints of the `i`th line are $(i, 0)$ and $(i, \text{height}[i])$.

Find two lines that together with the x-axis form a container, such that the container contains the most water.

Return the maximum amount of water a container can store.

Notice that you may not slant the container.

Example 1:

Input: `height = [1,8,6,2,5,4,8,3,7]` Output: 49 Explanation: The above vertical lines are represented by array `[1,8,6,2,5,4,8,3,7]`. In this case, the max area of water (blue section) the container can contain is 49.

Example 2:

Input: `height = [1,1]` Output: 1

Constraints:

```
n == height.length
2 <= n <= 105
0 <= height[i] <= 104
```

<https://leetcode.com/problems/container-with-most-water/description/>

Easy Solution

```
def easy_solution(height: List[int]) -> int:
    # Brute-force solution: Check all pairs of lines
    max_area = 0
    for i in range(len(height)):
        for j in range(i + 1, len(height)):
            area = min(height[i], height[j]) * (j - i)
            max_area = max(max_area, area)
    return max_area
```

Optimized Solution

```
def optimized_solution(height: List[int]) -> int:

Best Time to Buy and Sell Stock

You are given an array `prices` where `prices[i]` is the price of a given stock on the *i*th day.

You want to maximize your profit by choosing a single day to buy one stock and choosing a different day in the future to sell that stock.

Return the maximum profit you can achieve from this transaction. If you cannot achieve any profit, return 0.

Example 1:

Input: `prices = [7,1,5,3,6,4]` Output: 5 Explanation: Buy on day 2 (price = 1) and sell on day 5 (price = 6), profit = 6-1 = 5. Note that buying on day 2 and selling on day 1 is not allowed because you must buy before you sell.

Example 2:

Input: `prices = [7,6,4,3,1]` Output: 0 Explanation: In this case, no transactions are done and the max profit = 0.

Constraints:

```
1 <= prices.length <= 105
0 <= prices[i] <= 104
```

<https://leetcode.com/problems/best-time-to-buy-and-sell-stock/description/>

Easy Solution

```
def easy_solution(prices: List[int]) -> int:
    # Brute-force solution: Check every pair of days
    max_profit = 0
    for i in range(len(prices)):
        for j in range(i + 1, len(prices)):
            profit = prices[j] - prices[i]
            if profit > max_profit:
                max_profit = profit
    return max_profit
```

Optimized Solution

```
def optimized_solution(prices: List[int]) -> int:

Valid Palindrome

A phrase is a palindrome if, after converting all uppercase letters into lowercase letters and removing all non-alphanumeric characters, it reads the same forward and backward. Alphanumeric characters include letters and numbers.

Given a string *s*, return true if it is a palindrome, or false otherwise.

Example 1: Input: *s* = "A man, a plan, a canal: Panama" Output: true Explanation: "amanaplanacanalpanama" is a palindrome.

Example 2: Input: *s* = "race a car" Output: false Explanation: "raceacar" is not a palindrome.

Constraints: $1 \leq s.length \leq 2 * 10^5$ *s* consists only of printable ASCII characters.

<https://leetcode.com/problems/valid-palindrome/description/>

Easy Solution

```
def easy_solution(s: str) -> bool:
    # Brute-force solution: Clean string and check palindrome
    cleaned = ''.join(c.lower() for c in s if c.isalnum())
    return cleaned == cleaned[::-1]
```

Optimized Solution

```
def optimized_solution(s: str) -> bool:
    # Optimized solution: Use two pointers
    left, right = 0, len(s) - 1
    while left < right:
        while left < right and not s[left].isalnum():
            left += 1
        while left < right and not s[right].isalnum():
            right -= 1
        if s[left].lower() != s[right].lower():
            return False
        left += 1
        right -= 1
    return True
```

Time Complexity: $O(n)$ Space Complexity: $O(1)$

Valid Anagram

Given two strings *s* and *t*, return true if *t* is an anagram of *s*, and false otherwise.

An Anagram is a word or phrase formed by rearranging the letters of a different word or phrase, typically using all the original letters exactly once.

Example 1: Input: *s* = "anagram", *t* = "nagaram" Output: true

Example 2: Input: *s* = "rat", *t* = "car" Output: false

Constraints: $1 \leq s.length, t.length \leq 5 * 10^4$ *s* and *t* consist of lowercase English letters.

Follow up: What if the inputs contain Unicode characters? How would you adapt your solution to such a case?

<https://leetcode.com/problems/valid-anagram/description/>

Easy Solution

```
def easy_solution(s: str, t: str) -> bool:
    # Brute-force solution: Sort and compare
    return sorted(s) == sorted(t)
```

Optimized Solution

```
def optimized_solution(s: str, t: str) -> bool:
    # Optimized solution: Use hashmap to count characters
    if len(s) != len(t):
        return False
    char_count = {}
    for c in s:
        char_count[c] = char_count.get(c, 0) + 1
    for c in t:
        if c not in char_count:
            return False
        char_count[c] -= 1
        if char_count[c] == 0:
            del char_count[c]
    return len(char_count) == 0
```

Palindromic Substrings

Given a string *s*, return the number of palindromic substrings in it.

A string is a palindrome when it reads the same backward as forward.

A substring is a contiguous sequence of characters within the string.

Example 1: Input: *s* = "abc" Output: 3 Explanation: Three palindromic strings: "a", "b", "c".

Example 2: Input: *s* = "aaa" Output: 6 Explanation: Six palindromic strings: "a", "a", "a", "aa", "aa", "aaa".

Constraints: $1 \leq s.length \leq 1000$ *s* consists of lowercase English letters.

<https://leetcode.com/problems/palindromic-substrings/description/>

Easy Solution

```
def easy_solution(s: str) -> int:
    # Brute-force solution: Check all substrings
    def is_palindrome(sub: str) -> bool:
        return sub == sub[::-1]

    count = 0
    for i in range(len(s)):
        for j in range(i, len(s)):
            if is_palindrome(s[i:j+1]):
                count += 1
    return count
```

Optimized Solution

```
def optimized_solution(s: str) -> int:
    # Optimized solution: Expand around center
    def count_palindromes(left: int, right: int) -> int:
        count = 0
        while left >= 0 and right < len(s) and s[left] == s[right]:
            count += 1
            left -= 1
            right += 1
        return count

    total_count = 0
    for i in range(len(s)):
        total_count += count_palindromes(i, i) # Odd length
    for i in range(len(s)-1):
        total_count += count_palindromes(i, i+1) # Even length
    return total_count
```

Minimum Window Substring

Given two strings *s* and *t* of lengths *m* and *n* respectively, return the minimum window substring of *s* such that every character in *t* (including duplicates) is included in the window. If there is no such substring, return the empty string "".

The testcases will be generated such that the answer is unique.

Example 1: Input: *s* = "ADOBECODEBANC", *t* = "ABC" Output: "BANC" Explanation: The minimum window substring "BANC" includes 'A', 'B', and 'C' from string *t*.

Example 2: Input: *s* = "a", *t* = "a" Output: "a" Explanation: The entire string *s* is the minimum window.

Example 3: Input: *s* = "a", *t* = "aa" Output: "" Explanation: Both 'a's from *t* must be included in the window. Since the largest window of *s* only has one 'a', return empty string.

Constraints: $m == s.length$ $n == t.length$ $1 \leq m, n \leq 105$ *s* and *t* consist of uppercase and lowercase English letters.

Follow up: Could you find an algorithm that runs in $O(m + n)$ time?

Encode and Decode Strings

Design an algorithm to encode a list of strings to a string. The encoded string is then sent over the network and is decoded back to the original list of strings.

Implement the encode and decode methods.

Example: Input: ["Hello","World"] Output: ["Hello","World"]

Note:

1. The string may contain any possible characters out of 256 valid ascii characters. Your algorithm should be generalized enough to work on any possible characters.
2. Do not use class member/global/static variables to store states. Your encode and decode algorithms should be stateless.

<https://leetcode.com/problems/encode-and-decode-strings/description/>

Easy Solution

```
def easy_solution(strs: List[str]) -> List[str]:  
    # Utilize the Codec class for encoding and decoding  
    codec = Codec()  
    encoded = codec.encode(strs)  
    return codec.decode(encoded)
```

Optimized Solution

```
def optimized_solution(strs: List[str]) -> List[str]:

    return easy_solution(a, b)
```

Time Complexity: $O(1)$ Space Complexity: $O(1)$

Similar Questions

Add Binary

Reverse Bits

Reverse bits of a given 32 bits unsigned integer.

Note:

Note that in some languages, such as Java, there is no unsigned integer type. In this case, both input and output will be given as a signed integer type. They should not affect your implementation, as the integer's internal binary representation is the same, whether it is signed or unsigned.

In Java, the compiler represents the signed integers using 2's complement notation. Therefore, in Example 2 above, the input represents the signed integer -3 and the output represents the signed integer -1073741825.

Example 1:

Input: n = 00000010100101000001111010011100 Output: 964176192
(00111001011110000010100101000000) Explanation: The input binary string 00000010100101000001111010011100 represents the unsigned integer 43261596, so return 964176192 which its binary representation is 00111001011110000010100101000000.

Example 2:

Input: n = 1111111111111111111111111111101 Output: 3221225471
(10111111111111111111111111111111) Explanation: The input binary string 1111111111111111111111111111101 represents the unsigned integer 4294967293, so return 3221225471 which its binary representation is 10111111111111111111111111111111.

Constraints:

The input must be a binary string of length 32

Counting Bits

Given an integer n , return an array `ans` of length $n + 1$ such that for each i ($0 \leq i \leq n$), `ans[i]` is the number of 1's in the binary representation of i .

Example 1:

Input: $n = 2$ Output: `[0,1,1]` Explanation: 0 --> 0 1 --> 1 2 --> 10

Example 2:

Input: $n = 5$ Output: `[0,1,1,2,1,2]` Explanation: 0 --> 0 1 --> 1 2 --> 10 3 --> 11 4 --> 100 5 --> 101

Constraints:

$0 \leq n \leq 105$

<https://leetcode.com/problems/counting-bits/>

Easy Solution

```
def easy_solution(n: int) -> List[int]:
    # Iterative solution: Count bits for each number
    def count_bits(x: int) -> int:
        count = 0
        while x:
            count += x & 1
            x >>= 1
        return count

    return [count_bits(i) for i in range(n + 1)]
```

Optimized Solution

```
def optimized_solution(n: int) -> List[int]:
    # Optimized solution: Use dynamic programming
    dp = [0] * (n + 1)
    for i in range(1, n + 1):
        dp[i] = dp[i >> 1] + (i & 1)
    return dp
```

Time Complexity: $O(n)$ Space Complexity: $O(n)$

Reverse Linked List

Given the head of a singly linked list, reverse the list, and return the reversed list.

Example 1:

Input: head = [1,2,3,4,5] Output: [5,4,3,2,1]

Example 2:

Input: head = [1,2] Output: [2,1]

Example 3:

Input: head = [] Output: []

Constraints:

The number of nodes in the list is the range [0, 5000].
-5000 <= Node.val <= 5000

<https://leetcode.com/problems/reverse-linked-list/description/>

Easy Solution

```
def easy_solution(head: Optional[ListNode]) -> Optional[ListNode]:  
    # Iterative approach: Reverse the list by changing the next  
    pointers  
    prev = None  
    current = head  
    while current:  
        next_node = current.next  
        current.next = prev  
        prev = current  
        current = next_node  
    return prev
```

Optimized Solution

```
def optimized_solution(head: Optional[ListNode]) ->  
Optional[ListNode]:  
    # The easy solution is already optimal for this problem  
    return easy_solution(head)
```

Reorder List

You are given the head of a singly linked-list. The list can be represented as:

$L_0 \rightarrow L_1 \rightarrow \dots \rightarrow L_{n-1} \rightarrow L_n$

Reorder the list to be on the following form:

$L_0 \rightarrow L_n \rightarrow L_1 \rightarrow L_{n-1} \rightarrow L_2 \rightarrow L_{n-2} \rightarrow \dots$

You may not modify the values in the list's nodes. Only nodes themselves may be changed.

Example 1:

Input: head = [1,2,3,4] Output: [1,4,2,3]

Example 2:

Input: head = [1,2,3,4,5] Output: [1,5,2,4,3]

Constraints:

The number of nodes in the list is in the range $[1, 5 * 10^4]$.
 $1 \leq \text{Node.val} \leq 1000$

<https://leetcode.com/problems/reorder-list/description/>

Easy Solution

```
def easy_solution(head: Optional[ListNode]) -> None:
    # Optimal approach: Find middle, reverse second half, and merge
    if not head or not head.next:
        return

    # Find the middle of the list
    slow = fast = head
    while fast.next and fast.next.next:
        slow = slow.next
        fast = fast.next.next

    # Reverse the second half of the list
    second = slow.next
    slow.next = None
    prev = None
    while second:
        next_node = second.next
        second.next = prev
        prev = second
        second = next_node

    # Merge the two halves
    first = head
    second = prev
    while second:
        next_first = first.next
        next_second = second.next
        first.next = second
        second.next = next_first
        first = next_first
        second = next_second
```

```
second.next = next_first
first = next_first
second = next_second
```

Merge Two Sorted Lists

You are given the heads of two sorted linked lists list1 and list2.

Merge the two lists in a one sorted list. The list should be made by splicing together the nodes of the first two lists.

Return the head of the merged linked list.

Example 1:

Input: list1 = [1,2,4], list2 = [1,3,4] Output: [1,1,2,3,4,4]

Example 2:

Input: list1 = [], list2 = [] Output: []

Example 3:

Input: list1 = [], list2 = [0] Output: [0]

Constraints:

- The number of nodes in both lists is in the range [0, 50].
- $-100 \leq \text{Node.val} \leq 100$
- Both list1 and list2 are sorted in non-decreasing order.

<https://leetcode.com/problems/merge-two-sorted-lists/description/>

Easy Solution

```
def easy_solution(l1: Optional[ListNode], l2: Optional[ListNode]) ->
Optional[ListNode]:
    # Iterative approach: Merge two sorted lists
    dummy = ListNode(0)
    current = dummy
    while l1 and l2:
        if l1.val <= l2.val:
            current.next = l1
            l1 = l1.next
        else:
            current.next = l2
            l2 = l2.next
        current = current.next
    current.next = l1 if l1 else l2
    return dummy.next
```

Optimized Solution

Linked List Cycle

Given head, the head of a linked list, determine if the linked list has a cycle in it.

There is a cycle in a linked list if there is some node in the list that can be reached again by continuously following the next pointer. Internally, pos is used to denote the index of the node that tail's next pointer is connected to. Note that pos is not passed as a parameter.

Return true if there is a cycle in the linked list. Otherwise, return false.

Example 1:

Input: head = [3,2,0,-4], pos = 1 Output: true Explanation: There is a cycle in the linked list, where the tail connects to the 1st node (0-indexed).

Example 2:

Input: head = [1,2], pos = 0 Output: true Explanation: There is a cycle in the linked list, where the tail connects to the 0th node.

Example 3:

Input: head = [1], pos = -1 Output: false Explanation: There is no cycle in the linked list.

Constraints:

```
The number of the nodes in the list is in the range [0, 104].
-105 <= Node.val <= 105
pos is -1 or a valid index in the linked list.
```

<https://leetcode.com/problems/linked-list-cycle/description/>

Easy Solution

```
def easy_solution(head: Optional[ListNode]) -> bool:
    # Brute-force solution: Use a set to track visited nodes
    seen = set()
    current = head
    while current:
        if current in seen:
            return True
        seen.add(current)
        current = current.next
    return False
```

Optimized Solution

```
def optimized_solution(head: Optional[ListNode]) -> bool:
    # Optimized solution: Use two pointers (Floyd's Tortoise and Hare)
    if not head or not head.next:
        return False
    slow = head
    fast = head.next
    while slow != fast:
```

```
        if not fast or not fast.next:
            return False
        slow = slow.next
        fast = fast.next.next
    return True
```

Intersection of Two Linked Lists

Given the heads of two singly linked-lists headA and headB, return the node at which the two lists intersect. If the two linked lists have no intersection at all, return null.

For example, the following two linked lists begin to intersect at node c1:

Example 1:

Input: intersectVal = 8, listA = [4,1,8,4,5], listB = [5,6,1,8,4,5], skipA = 2, skipB = 3
Output: Intersected at '8' Explanation: The intersected node's value is 8 (note that this must not be 0 if the two lists intersect). From the head of A, it reads as [4,1,8,4,5]. From the head of B, it reads as [5,6,1,8,4,5]. There are 2 nodes before the intersected node in A; There are 3 nodes before the intersected node in B.

Example 2:

Input: intersectVal = 2, listA = [1,9,1,2,4], listB = [3,2,4], skipA = 3, skipB = 1 Output: Intersected at '2' Explanation: The intersected node's value is 2 (note that this must not be 0 if the two lists intersect). From the head of A, it reads as [1,9,1,2,4]. From the head of B, it reads as [3,2,4]. There are 3 nodes before the intersected node in A; There are 1 node before the intersected node in B.

Example 3:

Input: intersectVal = 0, listA = [2,6,4], listB = [1,5], skipA = 3, skipB = 2 Output: No intersection Explanation: From the head of A, it reads as [2,6,4]. From the head of B, it reads as [1,5]. Since the two lists do not intersect, intersectVal must be 0.

Constraints:

```
The number of nodes of listA is in the m.
The number of nodes of listB is in the n.
1 <= m, n <= 3 * 104
1 <= Node.val <= 105
0 <= skipA < m
0 <= skipB < n
intersectVal is 0 if listA and listB do not intersect.
intersectVal == listA[skipA] == listB[skipB] if listA and listB
intersect.
```

<https://leetcode.com/problems/intersection-of-two-linked-lists/description/>

Easy Solution

```
def easy_solution(headA: ListNode, headB: ListNode) ->
Optional[ListNode]:
    # Two-pointer approach: Find intersection node
    if not headA or not headB:
        return None

    nodeA = headA
    nodeB = headB

    while nodeA != nodeB:
        nodeA = nodeA.next if nodeA else headB
        nodeB = nodeB.next if nodeB else headA
```

```
return nodeA
```

Optimized Solution

```
def optimized_solution(headA: ListNode, headB: ListNode) ->
Optional[ListNode]:
    # The easy solution is already optimal for this problem
    return easy_solution(headA, headB)
```

Time Complexity: $O(n + m)$ Space Complexity: $O(1)$

Validate Binary Search Tree

Given the root of a binary tree, determine if it is a valid binary search tree (BST).

A valid BST is defined as follows:

The left subtree of a node contains only nodes with keys less than the node's key. The right subtree of a node contains only nodes with keys greater than the node's key. Both the left and right subtrees must also be binary search trees.

Example 1:

Input: root = [2,1,3] Output: true

Example 2:

Input: root = [5,1,4,null,null,3,6] Output: false Explanation: The root node's value is 5 but its right child's value is 4.

Constraints:

```
The number of nodes in the tree is in the range [1, 104].
-231 <= Node.val <= 231 - 1
```

<https://leetcode.com/problems/validate-binary-search-tree/>

Easy Solution

```
def easy_solution(root: Optional[TreeNode]) -> bool:
    # Recursive solution: Check each node's value within valid range
    def is_valid_bst(node: Optional[TreeNode], min_val: float,
max_val: float) -> bool:
        if not node:
            return True
        if node.val <= min_val or node.val >= max_val:
            return False
        return (is_valid_bst(node.left, min_val, node.val) and
                is_valid_bst(node.right, node.val, max_val))

    return is_valid_bst(root, float('-inf'), float('inf'))
```

Optimized Solution

```
def optimized_solution(root: Optional[TreeNode]) -> bool:
    # Iterative solution: Use a stack to check nodes
    stack = [(root, float('-inf'), float('inf'))]
    while stack:
        node, min_val, max_val = stack.pop()
        if not node:
            continue
        if node.val <= min_val or node.val >= max_val:
            return False
        stack.append((node.right, node.val, max_val))
        stack.append((node.left, min_val, node.val))
    return True
```

Serialize and Deserialize Binary Tree

Serialization is the process of converting a data structure or object into a sequence of bits so that it can be stored in a file or memory buffer, or transmitted across a network connection link to be reconstructed later in the same or another computer environment.

Design an algorithm to serialize and deserialize a binary tree. There is no restriction on how your serialization/deserialization algorithm should work. You just need to ensure that a binary tree can be serialized to a string and this string can be deserialized to the original tree structure.

Clarification: The input/output format is the same as how LeetCode serializes a binary tree. You do not necessarily need to follow this format, so please be creative and come up with different approaches yourself.

Example 1:

Input: root = [1,2,3,null,null,4,5] Output: [1,2,3,null,null,4,5]

Example 2:

Input: root = [] Output: []

Constraints:

The number of nodes in the tree is in the range [0, 104].
-1000 <= Node.val <= 1000

<https://leetcode.com/problems/serialize-and-deserialize-binary-tree/>

Easy Solution

```
def easy_solution(root: Optional[TreeNode]) -> Optional[TreeNode]:  
    # Use Codec class to serialize and deserialize  
    codec = Codec()  
    serialized = codec.serialize(root)  
    return codec.deserialize(serialized)
```

Optimized Solution

```
def optimized_solution(root: Optional[TreeNode]) ->  
Optional[TreeNode]:  
    # The easy solution is already optimal for this problem  
    return easy_solution(root)
```

Time Complexity: O(n) Space Complexity: O(n)

Minimum Depth of Binary Tree

Lowest Common Ancestor of a Binary Search Tree

Given a binary search tree (BST), find the lowest common ancestor (LCA) node of two given nodes in the BST.

According to the definition of LCA on Wikipedia: "The lowest common ancestor is defined between two nodes p and q as the lowest node in T that has both p and q as descendants (where we allow a node to be a descendant of itself)."

Example 1:

Input: root = [6,2,8,0,4,7,9,null,null,3,5], $p = 2$, $q = 8$ Output: 6 Explanation: The LCA of nodes 2 and 8 is 6.

Example 2:

Input: root = [6,2,8,0,4,7,9,null,null,3,5], $p = 2$, $q = 4$ Output: 2 Explanation: The LCA of nodes 2 and 4 is 2, since a node can be a descendant of itself according to the LCA definition.

Example 3:

Input: root = [2,1], $p = 2$, $q = 1$ Output: 2

Constraints:

- The number of nodes in the tree is in the range [2, 105].
- $-109 \leq \text{Node.val} \leq 109$
- All Node.val are unique.
- $p \neq q$
- p and q will exist in the BST.

<https://leetcode.com/problems/lowest-common-ancestor-of-a-binary-search-tree/>

Easy Solution

```
def easy_solution(root: Optional[TreeNode], p: TreeNode, q: TreeNode)
-> Optional[TreeNode]:
    # Recursive solution: Traverse the tree to find LCA
    if not root:
        return None

Kth Smallest Element in a BST

Given the root of a binary search tree, and an integer k, return the kth smallest value (1-indexed) of all the values of the nodes in the tree.

Example 1:

Input: root = [3,1,4,null,2], k = 1 Output: 1

Example 2:

Input: root = [5,3,6,2,4,null,null,1], k = 3 Output: 3

Constraints:

```
The number of nodes in the tree is n.  
1 <= k <= n <= 104  
0 <= Node.val <= 104
```

<https://leetcode.com/problems/kth-smallest-element-in-a-bst/>

Easy Solution

```
def easy_solution(root: Optional[TreeNode], k: int) -> int:  
    # Recursive solution: Inorder traversal to find kth smallest  
    def inorder(node: Optional[TreeNode]) -> None:  
        nonlocal k, result  
        if not node:  
            return  
        inorder(node.left)  
        k -= 1  
        if k == 0:  
            result = node.val  
            return  
        inorder(node.right)  
  
    result = None  
    inorder(root)  
    return result
```

Optimized Solution

```
def optimized_solution(root: Optional[TreeNode], k: int) -> int:  
    # Iterative solution: Inorder traversal using stack  
    stack = []  
    current = root  
  
    while current or stack:  
        while current:  
            stack.append(current)  
            current = current.left  
  
        current = stack.pop()  
        k -= 1  
        if k == 0:
```

```
        return current.val  
    current = current.right
```

Time Complexity: $O(H + k)$ Space Complexity: $O(H)$

Implement Trie (Prefix Tree)

A trie (pronounced as "try") or prefix tree is a tree data structure used to efficiently store and retrieve keys in a dataset of strings. There are various applications of this data structure, such as autocomplete and spellchecker.

Implement the Trie class:

```
Trie() Initializes the trie object.
void insert(String word) Inserts the string word into the trie.
boolean search(String word) Returns true if the string word is in the
trie (i.e., was inserted before), and false otherwise.
boolean startsWith(String prefix) Returns true if there is a
previously inserted string word that has the prefix prefix, and false
otherwise.
```

Example 1:

Input ["Trie", "insert", "search", "search", "startsWith", "insert", "search"] [[], ["apple"], ["apple"], ["app"], ["app"], ["app"], ["app"]] Output [null, null, true, false, true, null, true]

Explanation Trie trie = new Trie(); trie.insert("apple"); trie.search("apple"); // return True trie.search("app"); // return False trie.startsWith("app"); // return True trie.insert("app"); trie.search("app"); // return True

Constraints:

```
1 <= word.length, prefix.length <= 2000
word and prefix consist only of lowercase English letters.
At most 3 * 104 calls in total will be made to insert, search, and
startsWith.
```

<https://leetcode.com/problems/implement-trie-prefix-tree/>

Easy Solution

```
def easy_solution():
    # Use the Trie class to perform operations
    return Trie()
```

Optimized Solution

```
def optimized_solution():
    # The easy solution is already optimal for this problem
    return Trie()
```

Time Complexity: O(m) Space Complexity: O(m)

Construct Binary Tree from Preorder and Inorder Traversal

Given two integer arrays preorder and inorder where preorder is the preorder traversal of a binary tree and inorder is the inorder traversal of the same tree, construct and return the binary tree.

Example 1:

Input: preorder = [3,9,20,15,7], inorder = [9,3,15,20,7] Output: [3,9,20,null,null,15,7]

Example 2:

Input: preorder = [-1], inorder = [-1] Output: [-1]

Constraints:

```
1 <= preorder.length <= 3000
inorder.length == preorder.length
-3000 <= preorder[i], inorder[i] <= 3000
preorder and inorder consist of unique values.
Each value of inorder also appears in preorder.
preorder is guaranteed to be the preorder traversal of the tree.
inorder is guaranteed to be the inorder traversal of the tree.
```

<https://leetcode.com/problems/construct-binary-tree-from-preorder-and-inorder-traversal/>

Easy Solution

```
def easy_solution(preorder: List[int], inorder: List[int]) ->
Optional[TreeNode]:
    # Recursive solution: Use preorder and inorder to build the tree
    if not preorder or not inorder:
        return None
    root = TreeNode(preorder[0])
    mid = inorder.index(preorder[0])
    root.left = easy_solution(preorder[1:mid+1], inorder[:mid])
    root.right = easy_solution(preorder[mid+1:], inorder[mid+1:])
    return root
```

Optimized Solution

```
def optimized_solution(preorder: List[int], inorder: List[int]) ->
Optional[TreeNode]:
    # Optimized solution: Use a hashmap to quickly find the root in
inorder
    def build(start: int, end: int) -> Optional[TreeNode]:
        nonlocal pre_idx
        if start > end:
            return None
        root = TreeNode(preorder[pre_idx])
        pre_idx += 1
        mid = inorder_map[root.val]
```

```
        root.left = build(start, mid - 1)
        root.right = build(mid + 1, end)
        return root

pre_idx = 0
inorder_map = {val: idx for idx, val in enumerate(inorder)}
return build(0, len(inorder) - 1)
```

Time Complexity: $O(n)$ Space Complexity: $O(n)$

Similar Questions

Construct Binary Tree from Inorder and Postorder Traversal

Binary Tree Maximum Path Sum

A path in a binary tree is a sequence of nodes where each pair of adjacent nodes in the sequence has an edge connecting them. A node can only appear in the sequence at most once. Note that the path does not need to pass through the root.

The path sum of a path is the sum of the node's values in the path.

Given the root of a binary tree, return the maximum path sum of any path.

Example 1:

Input: root = [1,2,3] Output: 6

Example 2:

Input: root = [-10,9,20,null,null,15,7] Output: 42

Constraints:

The number of nodes in the tree is in the range $[1, 3 \times 10^4]$.
 $-1000 \leq \text{Node.val} \leq 1000$

<https://leetcode.com/problems/binary-tree-maximum-path-sum/>

Easy Solution

```
def easy_solution(root: Optional[TreeNode]) -> int:
    # Helper function to calculate the maximum gain from each node
    def max_gain(node: Optional[TreeNode]) -> int:
        nonlocal max_sum
        if not node:
            return 0
        left_gain = max(max_gain(node.left), 0)
        right_gain = max(max_gain(node.right), 0)
        path_sum = node.val + left_gain + right_gain
        max_sum = max(max_sum, path_sum)
        return node.val + max(left_gain, right_gain)

    max_sum = float('-inf')
    max_gain(root)
    return max_sum
```

Optimized Solution

```

Binary Tree Level Order Traversal

Given the root of a binary tree, return the level order traversal of its nodes' values. (i.e., from left to right, level by level).

Example 1:

Input: root = [3,9,20,null,null,15,7] Output: [[3],[9,20],[15,7]]

Example 2:

Input: root = [1] Output: [[1]]

Example 3:

Input: root = [] Output: []

Constraints:

The number of nodes in the tree is in the range [0, 2000].
-1000 <= Node.val <= 1000

<https://leetcode.com/problems/binary-tree-level-order-traversal/>

Easy Solution

```
def easy_solution(root: Optional[TreeNode]) -> List[List[int]]:
    # Iterative solution: Use a queue to traverse each level
    if not root:
        return []
    result = []
    queue = [root]
    while queue:
        level_size = len(queue)
        level = []
        for _ in range(level_size):
            node = queue.pop(0)
            level.append(node.val)
            if node.left:
                queue.append(node.left)
            if node.right:
                queue.append(node.right)
        result.append(level)
    return result
```

Optimized Solution

```
def optimized_solution(root: Optional[TreeNode]) -> List[List[int]]:
    # More optimized iterative solution: Use a queue to traverse each
level
    if not root:
        return []
    result = []
    level = [root]
    while level:
```

```
        result.append([node.val for node in level])
        level = [child for node in level for child in (node.left,
node.right) if child]
    return result

Word Break

Given a string *s* and a dictionary of strings *wordDict*, return true if *s* can be segmented into a space-separated sequence of one or more dictionary words.

Note that the same word in the dictionary may be reused multiple times in the segmentation.

Example 1:

Input: *s* = "leetcode", *wordDict* = ["leet","code"] Output: true Explanation: Return true because "leetcode" can be segmented as "leet code".

Example 2:

Input: *s* = "applepenapple", *wordDict* = ["apple","pen"] Output: true Explanation: Return true because "applepenapple" can be segmented as "apple pen apple". Note that you are allowed to reuse a dictionary word.

Example 3:

Input: *s* = "catsandog", *wordDict* = ["cats","dog","sand","and","cat"] Output: false

Constraints:

```
1 <= s.length <= 300
1 <= wordDict.length <= 1000
1 <= wordDict[i].length <= 20
s and wordDict[i] consist of only lowercase English letters.
All the strings of wordDict are unique.
```

<https://leetcode.com/problems/word-break/description/>

Easy Solution

```
def easy_solution(s: str, wordDict: List[str]) -> bool:
    # Dynamic programming solution with O(n^2) time complexity
    dp = [False] * (len(s) + 1)
    dp[0] = True
    for i in range(1, len(s) + 1):
        for j in range(i):
            if dp[j] and s[j:i] in wordDict:
                dp[i] = True
                break
    return dp[len(s)]
```

Optimized Solution

```

Word Break II

Unique Paths

There is a robot on an $m \times n$ grid. The robot is initially located at the top-left corner (i.e., `grid[0][0]`). The robot tries to move to the bottom-right corner (i.e., `grid[m-1][n-1]`). The robot can only move either down or right at any point in time.

Given the two integers m and n , return the number of possible unique paths that the robot can take to reach the bottom-right corner.

The test cases are generated so that the answer will be less than or equal to $2 * 10^9$.

Example 1:

Input: $m = 3, n = 7$ Output: 28

Example 2:

Input: $m = 3, n = 2$ Output: 3 Explanation: From the top-left corner, there are a total of 3 ways to reach the bottom-right corner:

1. Right -> Down -> Down
2. Down -> Down -> Right
3. Down -> Right -> Down

Constraints:

$1 \leq m, n \leq 100$

<https://leetcode.com/problems/unique-paths/description/>

Easy Solution

```
def easy_solution(m: int, n: int) -> int:
    # Dynamic programming solution with  $O(m * n)$  space complexity
    dp = [[1] * n for _ in range(m)]
    for i in range(1, m):
        for j in range(1, n):
            dp[i][j] = dp[i-1][j] + dp[i][j-1]
    return dp[m-1][n-1]
```

Longest Increasing Subsequence

Given an integer array `nums`, return the length of the longest strictly increasing subsequence.

Example 1:

Input: `nums = [10,9,2,5,3,7,101,18]` Output: 4 Explanation: The longest increasing subsequence is `[2,3,7,101]`, therefore the length is 4.

Example 2:

Input: `nums = [0,1,0,3,2,3]` Output: 4

Example 3:

Input: `nums = [7,7,7,7,7,7,7]` Output: 1

Constraints:

```
1 <= nums.length <= 2500
-104 <= nums[i] <= 104
```

Follow up: Can you come up with an algorithm that runs in $O(n \log(n))$ time complexity?

<https://leetcode.com/problems/longest-increasing-subsequence/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> int:
    # Dynamic programming solution with  $O(n^2)$  time complexity
    if not nums:
        return 0
    dp = [1] * len(nums)
    for i in range(1, len(nums)):
        for j in range(i):
            if nums[i] > nums[j]:
                dp[i] = max(dp[i], dp[j] + 1)
    return max(dp)
```

Optimized Solution

Jump Game

You are given an integer array `nums`. You are initially positioned at the array's first index, and each element in the array represents your maximum jump length at that position.

Return `true` if you can reach the last index, or `false` otherwise.

Example 1:

Input: `nums = [2,3,1,1,4]` Output: `true` Explanation: Jump 1 step from index 0 to 1, then 3 steps to the last index.

Example 2:

Input: `nums = [3,2,1,0,4]` Output: `false` Explanation: You will always arrive at index 3 no matter what. Its maximum jump length is 0, which makes it impossible to reach the last index.

Constraints:

```
1 <= nums.length <= 104
0 <= nums[i] <= 105
```

<https://leetcode.com/problems/jump-game/description/>

Easy Solution

```
def easy_solution(nums: List[int]) -> bool:
    # Greedy solution with O(n) time complexity
    max_reach = 0
    for i, jump in enumerate(nums):
        if i > max_reach:
            return False
        max_reach = max(max_reach, i + jump)
    return True
```

Optimized Solution

```
def optimized_solution(nums: List[int]) -> bool:
    # Optimized greedy solution
    last_pos = len(nums) - 1
    for i in range(len(nums) - 1, -1, -1):
        if i + nums[i] >= last_pos:
            last_pos = i
    return last_pos == 0
```

House Robber II

You are a professional robber planning to rob houses along a street. Each house has a certain amount of money stashed. All houses at this place are arranged in a circle. That means the first house is the neighbor of the last one. Meanwhile, adjacent houses have a security system connected, and it will automatically contact the police if two adjacent houses were broken into on the same night.

Given an integer array `nums` representing the amount of money of each house, return the maximum amount of money you can rob tonight without alerting the police.

Example 1:

Input: `nums = [2,3,2]` Output: 3 Explanation: You cannot rob house 1 (money = 2) and then rob house 3 (money = 2), because they are adjacent houses.

Example 2:

Input: `nums = [1,2,3,1]` Output: 4 Explanation: Rob house 1 (money = 1) and then rob house 3 (money = 3). Total amount you can rob = 1 + 3 = 4.

Example 3:

Input: `nums = [1,2,3]` Output: 3

Constraints:

```
1 <= nums.length <= 100
0 <= nums[i] <= 1000
```

<https://leetcode.com/problems/house-robber-ii/description/>

Easy Solution

Decode Ways

A message containing letters from A-Z can be encoded into numbers using the following mapping:

'A' -> "1" 'B' -> "2" ... 'Z' -> "26"

To decode an encoded message, all the digits must be grouped then mapped back into letters using the reverse of the mapping above (there may be multiple ways).

For example, "11106" can be mapped into:

"AAJF" with the grouping (1 1 10 6)
"KJF" with the grouping (11 10 6)

Note that the grouping (1 11 06) is invalid because "06" cannot be mapped into 'F' since "6" is different from "06".

Given a string *s* containing only digits, return the number of ways to decode it.

The test cases are generated so that the answer fits in a 32-bit integer.

Example 1:

Input: *s* = "12" Output: 2 Explanation: "12" could be decoded as "AB" (1 2) or "L" (12).

Example 2:

Input: *s* = "226" Output: 3 Explanation: "226" could be decoded as "BZ" (2 26), "VF" (22 6), or "BBF" (2 2 6).

Example 3:

Input: *s* = "06" Output: 0 Explanation: "06" cannot be mapped to "F" because of the leading zero ("6" is different from "06").

Constraints:

```
1 <= s.length <= 100
s contains only digits and may contain leading zero(s).
```

Combination Sum

Given an array of distinct integers candidates and a target integer target, return a list of all unique combinations of candidates where the chosen numbers sum to target. You may return the combinations in any order.

The same number may be chosen from candidates an unlimited number of times. Two combinations are unique if the frequency of at least one of the chosen numbers is different.

The test cases are generated such that the number of unique combinations that sum up to target is less than 150 combinations for the given input.

Example 1:

Input: candidates = [2,3,6,7], target = 7 Output: [[2,2,3],[7]] Explanation: 2 and 3 are the only numbers that can be combined to get 7. 2 can be used twice, and the combination [2,2,3] is valid. 7 can be used once, and the combination [7] is valid.

Example 2:

Input: candidates = [2,3,5], target = 8 Output: [[2,2,2,2],[2,3,3],[3,5]]

Example 3:

Input: candidates = [2], target = 1 Output: []

Constraints:

```
1 <= candidates.length <= 30
2 <= candidates[i] <= 40
All elements of candidates are distinct.
1 <= target <= 40
```

<https://leetcode.com/problems/combination-sum/description/>

Easy Solution

```
def easy_solution(candidates: List[int], target: int) ->
List[List[int]]:
    # Backtracking solution
    def backtrack(start: int, target: int, path: List[int]) -> None:
        if target == 0:
            result.append(path[:])
            return
        for i in range(start, len(candidates)):
            if candidates[i] > target:
                break
            path.append(candidates[i])
            backtrack(i, target - candidates[i], path)
            path.pop()

    result: List[List[int]] = []
    candidates.sort()
    backtrack(0, target, [])
    return result
```

Optimized Solution

```
def optimized_solution(candidates: List[int], target: int) ->
List[List[int]]:
    # Dynamic programming solution
    dp: List[List[List[int]]] = [[] for _ in range(target + 1)]
    dp[0] = [[]]

    for c in candidates:
        for i in range(c, target + 1):
            dp[i].extend([comb + [c] for comb in dp[i - c]])

    return dp[target]
```

Time Complexity: $O(n * \text{target})$ Space Complexity: $O(\text{target})$

Coin Change

You are given an integer array `coins` representing coins of different denominations and an integer amount representing a total amount of money.

Return the fewest number of coins that you need to make up that amount. If that amount of money cannot be made up by any combination of the coins, return -1.

You may assume that you have an infinite number of each kind of coin.

Example 1:

Input: `coins = [1,2,5]`, `amount = 11` Output: 3 Explanation: $11 = 5 + 5 + 1$

Example 2:

Input: `coins = [2]`, `amount = 3` Output: -1

Example 3:

Input: `coins = [1]`, `amount = 0` Output: 0

Constraints:

```
1 <= coins.length <= 12
1 <= coins[i] <= 231 - 1
0 <= amount <= 104
```

<https://leetcode.com/problems/coin-change/description/>

Easy Solution

```
def easy_solution(coins: List[int], amount: int) -> int:
    # Dynamic programming solution with O(amount * len(coins)) time
    complexity
    dp = [float('inf')] * (amount + 1)
    dp[0] = 0
    for coin in coins:
        for x in range(coin, amount + 1):
            dp[x] = min(dp[x], dp[x - coin] + 1)
    return dp[amount] if dp[amount] != float('inf') else -1
```

Optimized Solution

```
def optimized_solution(coins: List[int], amount: int) -> int:
    # Optimized dynamic programming solution
    dp = [float('inf')] * (amount + 1)
    dp[0] = 0
    for i in range(1, amount + 1):
        dp[i] = min(dp[i - c] if i - c >= 0 else float('inf') for c in
coins) + 1
    return dp[amount] if dp[amount] != float('inf') else -1
```

Time Complexity: $O(\text{amount} * \text{len}(\text{coins}))$ Space Complexity: $O(\text{amount})$

Climbing Stairs

You are climbing a staircase. It takes n steps to reach the top.

Each time you can either climb 1 or 2 steps. In how many distinct ways can you climb to the top?

Example 1:

Input: $n = 2$ Output: 2 Explanation: There are two ways to climb to the top.

1. 1 step + 1 step
2. 2 steps

Example 2:

Input: $n = 3$ Output: 3 Explanation: There are three ways to climb to the top.

1. 1 step + 1 step + 1 step
2. 1 step + 2 steps
3. 2 steps + 1 step

Constraints:

$$1 \leq n \leq 45$$

<https://leetcode.com/problems/climbing-stairs/description/>

Easy Solution

```
def easy_solution(n: int) -> int:
    # Dynamic programming solution with O(n) space complexity
    if n <= 2:
        return n
    dp = [0] * (n + 1)
    dp[1] = 1
    dp[2] = 2
    for i in range(3, n + 1):
        dp[i] = dp[i - 1] + dp[i - 2]
    return dp[n]
```

Optimized Solution

```
def optimized_solution(n: int) -> int:
    # Optimized solution with O(1) space complexity
    if n <= 2:
        return n
    a, b = 1, 2
    for _ in range(3, n + 1):

Pacific Atlantic Water Flow

There is an $m \times n$ rectangular island that borders both the Pacific Ocean and Atlantic Ocean. The Pacific Ocean touches the island's left and top edges, and the Atlantic Ocean touches the island's right and bottom edges.

The island is partitioned into a grid of square cells. You are given an $m \times n$ integer matrix `heights` where `heights[r][c]` represents the height above sea level of the cell at coordinate (r, c) .

The island receives a lot of rain, and the rain water can flow to neighboring cells directly north, south, east, and west if the neighboring cell's height is less than or equal to the current cell's height. Water can flow from any cell adjacent to an ocean into the ocean.

Return a 2D list of grid coordinates `result` where `result[i] = [ri, ci]` denotes that rain water can flow from cell (ri, ci) to both the Pacific and Atlantic oceans.

Example 1:

Input: `heights = [[1,2,2,3,5],[3,2,3,4,4],[2,4,5,3,1],[6,7,1,4,5],[5,1,1,2,4]]` Output: `[[0,4],[1,3],[1,4],[2,2],[3,0],[3,1],[4,0]]` Explanation: The following cells can flow to the Pacific and Atlantic oceans, as shown below:
[0,4]: [0,4] -> Pacific Ocean [0,4] -> Atlantic Ocean
[1,3]: [1,3] -> Pacific Ocean [1,3] -> Atlantic Ocean
[1,4]: [1,4] -> Pacific Ocean [1,4] -> Atlantic Ocean
[2,2]: [2,2] -> Pacific Ocean [2,2] -> Atlantic Ocean
[3,0]: [3,0] -> Pacific Ocean [3,0] -> Atlantic Ocean
[3,1]: [3,1] -> Pacific Ocean [3,1] -> Atlantic Ocean
[4,0]: [4,0] -> Pacific Ocean [4,0] -> Atlantic Ocean

Example 2:

Input: `heights = [[1]]` Output: `[[0,0]]` Explanation: The water can flow from the only cell to the Pacific and Atlantic oceans.

Constraints:

```
m == heights.length
n == heights[i].length
1 <= m, n <= 200
0 <= heights[i][j] <= 105
```

Course Schedule

There are a total of `numCourses` courses you have to take, labeled from 0 to `numCourses - 1`. You are given an array `prerequisites` where `prerequisites[i] = [ai, bi]` indicates that you must take course `bi` first if you want to take course `ai`.

For example, the pair `[0, 1]`, indicates that to take course 0 you have to first take course 1.

Return true if you can finish all courses. Otherwise, return false.

Example 1:

Input: `numCourses = 2, prerequisites = [[1,0]]` Output: true Explanation: There are a total of 2 courses to take. To take course 1 you should have finished course 0. So it is possible.

Example 2:

Input: `numCourses = 2, prerequisites = [[1,0],[0,1]]` Output: false Explanation: There are a total of 2 courses to take. To take course 1 you should have finished course 0, and to take course 0 you should have finished course 1. So it is impossible.

Constraints:

```
1 <= numCourses <= 2000
0 <= prerequisites.length <= 5000
prerequisites[i].length == 2
0 <= ai, bi < numCourses
All the pairs prerequisites[i] are unique.
```

Clone Graph

Given a reference of a node in a connected undirected graph.

Return a deep copy (clone) of the graph.

Each node in the graph contains a value (int) and a list (List[Node]) of its neighbors.

```
class Node { public int val; public List neighbors; }
```

Test case format:

For simplicity, each node's value is the same as the node's index (1-indexed). For example, the first node with `val == 1`, the second node with `val == 2`, and so on. The graph is represented in the test case using an adjacency list.

An adjacency list is a collection of unordered lists used to represent a finite graph. Each list describes the set of neighbors of a node in the graph.

The given node will always be the first node with `val = 1`. You must return the copy of the given node as a reference to the cloned graph.

Example 1:

Input: `adjList = [[2,4],[1,3],[2,4],[1,3]]` Output: `[[2,4],[1,3],[2,4],[1,3]]` Explanation: There are 4 nodes in the graph. 1's neighbors are 2 and 4. 2's neighbors are 1 and 3. 3's neighbors are 2 and 4. 4's neighbors are 1 and 3.

Example 2:

Input: `adjList = [[]]` Output: `[[]]` Explanation: Note that the input contains one empty list. The graph consists of only one node with `val = 1` since there are no neighbors.

Example 3:

Input: `adjList = []` Output: `[]` Explanation: This an empty graph, it does not have any nodes.

Constraints:

- The number of nodes in the graph is in the range `[0, 100]`.
- `1 <= Node.val <= 100`
- `Node.val` is unique for each node.
- There are no repeated edges and no self-loops in the graph.
- The Graph is connected and all nodes can be visited starting from the given node.

Easy Solution

```
def easy_solution(node: Optional[Node]) -> Optional[Node]:
    # Easy solution: DFS with recursion to clone the graph
    if not node:
        return None

    visited = {}
```

```

def dfs(node: Node) -> Node:
    if node in visited:
        return visited[node]

    clone = Node(node.val)
    visited[node] = clone

    for neighbor in node.neighbors:
        clone.neighbors.append(dfs(neighbor))

    return clone

return dfs(node)

```

Optimized Solution

```

def optimized_solution(node: Optional[Node]) -> Optional[Node]:
    # Optimized solution: BFS with queue to clone the graph
    if not node:
        return None

    visited = {}
    queue = deque([node])
    visited[node] = Node(node.val)

    while queue:
        current = queue.popleft()
        for neighbor in current.neighbors:
            if neighbor not in visited:
                visited[neighbor] = Node(neighbor.val)
                queue.append(neighbor)
            visited[current].neighbors.append(visited[neighbor])

    return visited[node]

```

Alien Dictionary

There is a new alien language that uses the English alphabet. However, the order among letters are unknown to you.

You are given a list of strings words from the alien language's dictionary, where the strings in words are sorted lexicographically by the rules of this new language.

Return a string of the unique letters in the new alien language sorted in lexicographically increasing order by the new language's rules. If there is no solution, return "". If there are multiple solutions, return any of them.

A string *s* is lexicographically smaller than a string *t* if at the first letter where they differ, the letter in *s* comes before the letter in *t* in the alien language. If the first $\min(s.length, t.length)$ letters are the same, then *s* is smaller if and only if $s.length < t.length$.

Example 1:

Input: words = ["wrt","wrf","er","ett","rftt"] Output: "wertf"

Example 2:

Input: words = ["z","x"] Output: "zx"

Example 3:

Input: words = ["z","x","z"] Output: "" Explanation: The order is invalid, so return "".

Constraints:

```
1 <= words.length <= 100
1 <= words[i].length <= 100
words[i] consists of only lowercase English letters.
```

Non-overlapping Intervals

Given an array of intervals `intervals` where `intervals[i] = [starti, endi]`, return the minimum number of intervals you need to remove to make the rest of the intervals non-overlapping.

Example 1:

Input: `intervals = [[1,2],[2,3],[3,4],[1,3]]` Output: 1 Explanation: `[1,3]` can be removed and the rest of the intervals are non-overlapping.

Example 2:

Input: `intervals = [[1,2],[1,2],[1,2]]` Output: 2 Explanation: You need to remove two `[1,2]` to make the rest of the intervals non-overlapping.

Example 3:

Input: `intervals = [[1,2],[2,3]]` Output: 0 Explanation: You don't need to remove any of the intervals since they're already non-overlapping.

Constraints:

```
1 <= intervals.length <= 105
intervals[i].length == 2
-5 * 104 <= starti < endi <= 5 * 104
```

<https://leetcode.com/problems/non-overlapping-intervals/description/>

Easy Solution

```
def easy_solution(intervals: List[List[int]]) -> int:
    # Easy solution: Sort by end time and count overlaps
    if not intervals:
        return 0

    intervals.sort(key=lambda x: x[1])
    count = 0
    end = float('-inf')

    for interval in intervals:
        if interval[0] >= end:
            end = interval[1]
        else:
            count += 1

    return count
```

Optimized Solution

```
def optimized_solution(intervals: List[List[int]]) -> int:

Insert Interval

You are given an array of non-overlapping intervals `intervals` where `intervals[i] = [starti, endi]` represent the start and the end of the *i*th interval and `intervals` is sorted in ascending order by `starti`. You are also given an interval `newInterval = [start, end]` that represents the start and end of another interval.

Insert `newInterval` into `intervals` such that `intervals` is still sorted in ascending order by `starti` and `intervals` still does not have any overlapping intervals (merge overlapping intervals if necessary).

Return `intervals` after the insertion.

Example 1:

Input: `intervals = [[1,3],[6,9]]`, `newInterval = [2,5]` Output: `[[1,5],[6,9]]`

Example 2:

Input: `intervals = [[1,2],[3,5],[6,7],[8,10],[12,16]]`, `newInterval = [4,8]` Output: `[[1,2],[3,10],[12,16]]` Explanation: Because the new interval `[4,8]` overlaps with `[3,5]`, `[6,7]`, `[8,10]`.

Constraints:

```
0 <= intervals.length <= 104
intervals[i].length == 2
0 <= starti <= endi <= 105
intervals is sorted by starti in ascending order.
newInterval.length == 2
0 <= start <= end <= 105
```

<https://leetcode.com/problems/insert-interval/description/>

Easy Solution

```
def easy_solution(intervals: List[List[int]], newInterval: List[int])
-> List[List[int]]:
    # Easy solution: Iterate through intervals, merge if overlapping,
    otherwise append directly
    result = []
    i = 0
    n = len(intervals)

    # Add intervals before newInterval
    while i < n and intervals[i][1] < newInterval[0]:
        result.append(intervals[i])
        i += 1

    # Merge overlapping intervals
    while i < n and intervals[i][0] <= newInterval[1]:
        newInterval[0] = min(newInterval[0], intervals[i][0])
        newInterval[1] = max(newInterval[1], intervals[i][1])
        i += 1

    result.append(newInterval)

    # Add remaining intervals
```

```
while i < n:
    result.append(intervals[i])
    i += 1

return result
```

Optimized Solution

Set Matrix Zeroes

Given an $m \times n$ integer matrix `matrix`, if an element is 0, set its entire row and column to 0's.

You must do it in place.

Example 1:

Input: `matrix = [[1,1,1],[1,0,1],[1,1,1]]` Output: `[[1,0,1],[0,0,0],[1,0,1]]`

Example 2:

Input: `matrix = [[0,1,2,0],[3,4,5,2],[1,3,1,5]]` Output: `[[0,0,0,0],[0,4,5,0],[0,3,1,0]]`

Constraints:

```
m == matrix.length
n == matrix[0].length
1 <= m, n <= 200
-231 <= matrix[i][j] <= 231 - 1
```

<https://leetcode.com/problems/set-matrix-zeroes/description/>

Easy Solution

```
def easy_solution(matrix: List[List[int]]) -> None:
    # Brute-force solution: Use sets to track zero rows and columns
    m, n = len(matrix), len(matrix[0])
    zero_rows, zero_cols = set(), set()

    for i in range(m):
        for j in range(n):
            if matrix[i][j] == 0:
                zero_rows.add(i)
                zero_cols.add(j)

    for i in range(m):
        for j in range(n):
            if i in zero_rows or j in zero_cols:
                matrix[i][j] = 0
```

Optimized Solution

```
def optimized_solution(matrix: List[List[int]]) -> None:
    # Optimized solution: Use first row and column as markers
    m, n = len(matrix), len(matrix[0])
    first_row_zero = False
    first_col_zero = False

    # Check if the first row has any zeros
    for j in range(n):
        if matrix[0][j] == 0:
            first_row_zero = True
            break
```

```

# Check if the first column has any zeros
for i in range(m):
    if matrix[i][0] == 0:
        first_col_zero = True
        break

# Use first row and column to mark zeros
for i in range(1, m):
    for j in range(1, n):
        if matrix[i][j] == 0:
            matrix[i][0] = 0
            matrix[0][j] = 0

# Set matrix elements to zero based on markers
for i in range(1, m):
    for j in range(1, n):
        if matrix[i][0] == 0 or matrix[0][j] == 0:
            matrix[i][j] = 0

# Set the first row to zero if needed
if first_row_zero:
    for j in range(n):
        matrix[0][j] = 0

# Set the first column to zero if needed
if first_col_zero:
    for i in range(m):
        matrix[i][0] = 0

```

Rotate Image

You are given an $n \times n$ 2D matrix representing an image, rotate the image by 90 degrees (clockwise).

You have to rotate the image in-place, which means you have to modify the input 2D matrix directly. DO NOT allocate another 2D matrix and do the rotation.

Example 1:

Input: matrix = [[1,2,3],[4,5,6],[7,8,9]] Output: [[7,4,1],[8,5,2],[9,6,3]]

Example 2:

Input: matrix = [[5,1,9,11],[2,4,8,10],[13,3,6,7],[15,14,12,16]] Output: [[15,13,2,5],[14,3,4,1],[12,6,8,9],[16,7,10,11]]

Constraints:

```
n == matrix.length == matrix[i].length
1 <= n <= 20
-1000 <= matrix[i][j] <= 1000
```

<https://leetcode.com/problems/rotate-image/description/>

Easy Solution

```
def easy_solution(matrix: List[List[int]]) -> None:
    # Brute-force solution: Transpose the matrix, then reverse each
row    n = len(matrix)

    # Transpose the matrix
    for i in range(n):
        for j in range(i, n):
            matrix[i][j], matrix[j][i] = matrix[j][i], matrix[i][j]

    # Reverse each row
    for i in range(n):
        matrix[i].reverse()
```

Optimized Solution

```
def optimized_solution(matrix: List[List[int]]) -> None:
    # Optimized solution: Rotate four rectangles
    n = len(matrix)

    # Rotate four rectangles
    for i in range(n // 2 + n % 2):
        for j in range(n // 2):
            tmp = matrix[n - 1 - j][i]
            matrix[n - 1 - j][i] = matrix[n - 1 - i][n - j - 1]
            matrix[n - 1 - i][n - j - 1] = matrix[j][n - 1 - i]
            matrix[j][n - 1 - i] = matrix[i][j]
            matrix[i][j] = tmp
```

Time Complexity: $O(n^2)$ Space Complexity: $O(1)$

Determine Whether Matrix Can Be Obtained By Rotation

Top K Frequent Elements

Given an integer array `nums` and an integer `k`, return the `k` most frequent elements. You may return the answer in any order.

Example 1:

Input: `nums = [1,1,1,2,2,3]`, `k = 2` Output: `[1,2]`

Example 2:

Input: `nums = [1]`, `k = 1` Output: `[1]`

Constraints:

```
1 <= nums.length <= 105
-104 <= nums[i] <= 104
k is in the range [1, the number of unique elements in the array].
It is guaranteed that the answer is unique.
```

<https://leetcode.com/problems/top-k-frequent-elements/description/>

Easy Solution

```
def easy_solution(nums: List[int], k: int) -> List[int]:
    # Brute-force solution: Use a heap to find the k most frequent
elements
    count = {}
    for num in nums:
        count[num] = count.get(num, 0) + 1

    return heapq.nlargest(k, count.keys(), key=count.get)
```

Optimized Solution

```
def optimized_solution(nums: List[int], k: int) -> List[int]:
    # Optimized solution: Use bucket sort to find the k most frequent
elements
    count = {}
    freq = [[] for _ in range(len(nums) + 1)]

    for num in nums:
        count[num] = count.get(num, 0) + 1
    for num, c in count.items():
        freq[c].append(num)

    res = []
    for i in range(len(freq) - 1, 0, -1):
        for num in freq[i]:
            res.append(num)
            if len(res) == k:
                return res
```

Merge k Sorted Lists

You are given an array of k linked-lists lists, each linked-list is sorted in ascending order. Merge all the linked-lists into one sorted linked-list and return it.

Example 1:

Input: lists = [[1,4,5],[1,3,4],[2,6]] Output: [1,1,2,3,4,4,5,6] Explanation: The linked-lists are: [1->4->5, 1->3->4, 2->6] merging them into one sorted list: 1->1->2->3->4->4->5->6

Example 2:

Input: lists = [] Output: []

Example 3:

Input: lists = [[]] Output: []

Constraints:

```
k == lists.length
0 <= k <= 104
0 <= lists[i].length <= 500
-104 <= lists[i][j] <= 104
lists[i] is sorted in ascending order.
The sum of lists[i].length will not exceed 104.
```

<https://leetcode.com/problems/merge-k-sorted-lists/description/>

Easy Solution

```
def easy_solution(lists: List[ListNode]) -> ListNode:
    # Brute-force solution: Collect all nodes and sort them
    nodes = []
    head = point = ListNode(0)
    for l in lists:
        while l:
            nodes.append(l.val)
            l = l.next
    for x in sorted(nodes):
        point.next = ListNode(x)
        point = point.next
    return head.next
```

Optimized Solution

```
def optimized_solution(lists: List[ListNode]) -> ListNode:
    # Optimized solution: Use a heap to merge lists
    heap = []
    for i, l in enumerate(lists):
        if l:
            heapq.heappush(heap, (l.val, i, l))
```

```
dummy = ListNode(0)
curr = dummy
while heap:
    val, i, node = heapq.heappop(heap)
    curr.next = ListNode(val)
    curr = curr.next
    if node.next:
        heapq.heappush(heap, (node.next.val, i, node.next))

return dummy.next
```

Time Complexity: $O(N \log k)$ Space Complexity: $O(k)$

Find Median from Data Stream

The MedianFinder class has two methods:

void addNum(int num) - Adds the integer num from the data stream to the data structure. double findMedian() - Returns the median of all elements so far. Answers within 10⁻⁵ of the actual answer will be accepted.

Implement the MedianFinder class: MedianFinder() initializes the MedianFinder object. void addNum(int num) adds the integer num from the data stream to the data structure. double findMedian() returns the median of all elements so far. Answers within 10⁻⁵ of the actual answer will be accepted.

Example 1:

Input ["MedianFinder", "addNum", "addNum", "findMedian", "addNum", "findMedian"]
[[], [1], [2], [], [3], []] Output [null, null, null, 1.5, null, 2.0]

Explanation MedianFinder medianFinder = new MedianFinder();
medianFinder.addNum(1); // arr = [1] medianFinder.addNum(2); // arr = [1, 2]
medianFinder.findMedian(); // return 1.5 (i.e., (1 + 2) / 2) medianFinder.addNum(3); // arr[1, 2, 3] medianFinder.findMedian(); // return 2.0

Constraints:

```
-105 <= num <= 105  
There will be at least one element in the data structure before  
calling findMedian.  
At most 5 * 104 calls will be made to addNum and findMedian.
```

<https://leetcode.com/problems/find-median-from-data-stream/description/>

Easy Solution

```
def easy_solution() -> MedianFinder:  
    return MedianFinder()
```

Optimized Solution

```
def optimized_solution() -> MedianFinder:  
    return MedianFinder()
```

Time Complexity: O(log n) for addNum, O(1) for findMedian Space Complexity: O(n)
